

PageSpeed Insights Analysis - HelloGrowthCRM (Mobile)

1. PageSpeed Insights Screenshot

Mobile performance report for <https://hellogrowthcrm.com> captured from PageSpeed Insights.

2. Top 3 fixes I would make

Optimize and preload the hero image

Improves: LCP

Expected impact: Reduce from 5.6 s to about 3.5-4.0 s (roughly 1.5-2.0 s faster)

The hero image is likely the largest visible element on first load. Compressing it to WebP/AVIF, reducing its size, and preloading it would significantly improve LCP.

Reduce unused JavaScript and defer third-party scripts

Improves: INP

Expected impact: Reduce from 213 ms to about 120-160 ms (roughly 50-90 ms better)

Non-critical JavaScript can block the main thread and delay interactions. Deferring unused or third-party scripts would improve responsiveness.

Keep reserving space for images and dynamic elements

Improves: CLS

Expected impact: CLS is already 0, so the goal is to maintain this good score

Adding explicit width and height attributes and reserving space for dynamic content helps prevent layout shifts during loading.

3. One SEO problem visible in page source

The homepage uses multiple H1 headings instead of a single primary H1. This can make the main topic of the page less clear to search engines and is a common on-page SEO issue.

Why I chose these fixes

I focused on the metrics that have the biggest impact on mobile user experience: LCP for loading speed, INP for responsiveness, and CLS for visual stability. These changes are relatively high-impact and can be implemented without a complete redesign of the page.
